                                                                                                                                                                                                                 SUBCELLULAR LOCATION: Nuclear; associated with chromatin. Colocalizes with many PCG sites on polytene chromosomes. It also associates with many unique sites on polytene chromosomes. TISSUE SPECIFICITY: Highly expressed in murse cells and deposited in occytes late in oogenesis. Ubiquitous in early embryos. Late embryos show higher levels in CNS and neurectoderm. DEVELOPMENTAL STAGE: Expressed both maternally and zygotically. Early embryos have high levels of expression, this drops off and zygotic expression begins at 3-6 hour embryos. Expression levels are low in larvae and medium in pupae and adults. DOWAIN: Contains two Leu-Xaa-Xaa-Leu-Leu (LXXLL) motifs, which mabe required for an association with nuclear receptors (By
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      PCG and trxG proteins act by forming multiprotein complexes, which are respectively required to maintain the transcriptionally repressive and transcriptionally active state of homeotic genes throughout development. PcG and trxG protein complexes are not required to initiate repression and activation, but to maintain it during later stages of development. Both complexes probably act via methylation of histones, rendering chromatin heritably changed in its expressibility.
                                                                                                                                                                       similarity).

associated zinc finger protein (MAZ) ";
J. Biol. Chem. 273:20603-20614(1998)
-i- FUNCTION: MAY FUNCTION AS A TRANSCRIPTION FACTOR WITH DUAL ROLES
IN TRANSCRIPTION INITIATION AND TERMINATION. BINNS TO TWO SITES,
MEIA1 AND MEIA2, WITHIN THE C-MYC PROMOTER HAVING GREATER
AFFINITY FOR THE FORWER. ALSO BINDS TO MULTIPLE G/C-RICH SITES
WITHIN THE PROMOTER OF THE SP1 FAMILY OF TRANSCRIPTION FACTORS.
-i- SUBCELLULAR LOCATION: Nuclear (Probable).
-i- TISSUE SPECIFICITY: HEART, BRAIN, PLACENTA, LUNG, LIVER, SKELETAL
MUSCLE, AND PANCREAS. SEEMS NOT TO BE EXPRESSED IN KIDNEY.
-i- SIMILARITY: Contains 6 C2H2-type zinc fingers.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                responds
